## **ABSTRACT**

In this work, a comprehensive investigation of 1-(Chloromethyl)anthraquinone (CMAQ) was carried out using a combination of spectroscopic, quantum chemical, molecular docking, and in vitro cytotoxicity approaches to evaluate its potential as an anticancer candidate. The molecular structure was optimized using Density Functional Theory (DFT) at the B3LYP/cc-pVTZ level, confirming a stable  $C_1$  point group geometry with a HOMO–LUMO energy gap of 4.18 eV, indicative of moderate chemical reactivity and stability. Frontier molecular orbital analysis, global reactivity descriptors, Mulliken charge distribution, and Molecular Electrostatic Potential mapping revealed electron-rich carbonyl oxygen atoms as favorable electrophilic sites and a chloromethyl substituent susceptible to nucleophilic substitution. Vibrational assignments from FT-IR and FT-Raman spectra were consistent with theoretical predictions, validating the computational model. Time-dependent DFT simulations showed excellent agreement with experimental UV–Vis absorption, confirming  $n \to \pi^*$  transitions characteristic of anthraquinone derivatives. Molecular docking studies demonstrated stronger binding affinity of CMAQ toward DPP-4 (–7.42 kcal/mol) compared with p38 $\alpha$  MAPK (–6.21 kcal/mol). In vitro cytotoxicity assays revealed potent activity of CMAQ against A549 lung cancer cells (IC $_{50} = 4.12~\mu g/mL$ ) and moderate activity against HeLa cervical cancer cells (IC $_{50} = 13.25~\mu g/mL$ ), with apoptosis-like morphological changes confirmed microscopically. Overall, the integrated findings highlight CMAQ as a promising lead compound with preferential efficacy against lung cancer, supported by both computational and experimental evidence.

# INTRODUCTION

Anthraquinone and its derivatives represent an important class of aromatic compounds widely used in dyes, pigments, photodynamic agents, and pharmaceutical [1,2]. The quinone scaffold, characterized by its conjugated  $\pi$ -system and reactive carbonyl groups, imparts unique redox properties that underpin a broad range of biological and therapeutic activities, including anticancer, antibacterial, and antiviral effects [3-5]. Structural modifications at different positions of the anthraquinone core significantly alter physicochemical behavior, intermolecular interactions, and biological profiles [6].

Among substituted anthraquinones, halogenated derivatives have gained particular attention due to the ability of halogen substituents to modulate lipophilicity, membrane permeability,

and binding affinity toward biomolecular targets [7,8]. In this context,

1-(Chloromethyl)anthraquinone (CMAQ) is of considerable interest as the chloromethyl substituent introduces both an electron-withdrawing effect and a potentially reactive site, thereby influencing conjugation, charge distribution, and molecular recognition.

Recent advances in computational chemistry and spectroscopic characterization enable a deeper understanding of anthraquinone derivatives at the molecular level. Density Functional Theory (DFT) calculations provide reliable predictions of optimized geometries, vibrational frequencies, and electronic properties, while FT-IR and FT-Raman spectroscopy serve as experimental complements for vibrational assignment [9,10]. Moreover, Frontier Molecular Orbital (FMO) analysis, global

reactivity descriptors, and Molecular Electrostatic Potential (MEP) mapping allow identification of reactive sites, which are crucial for understanding ligand-target interactions.

In parallel, molecular docking studies offer a computational approach to predict the binding affinity and mode of interaction of anthraquinones with biological macromolecules, providing insights into their therapeutic potential [11,12]. Finally, in vitro cytotoxicity assays\*\* against human cancer cell lines provide experimental validation of the predicted bioactivity, bridging the gap between theoretical modeling and biomedical applications [13].

The present work integrates spectroscopic, quantum chemical, molecular docking, and in vitro cytotoxicity studies of CMAQ with the objective of assessing its potential as a novel cervical cancer drug candidate. By combining DFT-based structural and vibrational analysis, electronic property evaluation, molecular docking simulations, and biological assays, this study aims to establish a comprehensive molecular fingerprint of CMAQ and highlight its therapeutic relevance.

#### 2. Materials and Methods

## 2.1 Experimental Characterizations

The 1-(Chloromethyl) anthraquinone (CMAQ) compound, with a purity of 98%, was purchased from Sigma-Aldrich Chemicals Co. (St. Louis, MO, USA) and used without further purification. The Fourier Transform Infrared (FT-IR) spectrum was recorded at room temperature in the 4000-400 cm<sup>-1</sup> region using a PerkinElmer Spectrum 1 spectrometer and the KBr pellet technique, with a spectral resolution of 1 cm<sup>-1</sup>. The Fourier Transform Raman (FT-Raman) spectrum was collected with a Bruker RFS 27 spectrometer equipped with a Nd:YAG laser (1064 nm excitation), using a spectral resolution of 2 cm<sup>-1</sup>. Both FT-IR and FT-Raman spectra were measured in the 3500-400 cm<sup>-1</sup> region. The ultraviolet-visible (UV-Vis) absorption spectrum was obtained on a Shimadzu UV-3600 UV-Vis-NIR spectrophotometer in the range of 200-600 nm, using ethanol as the solvent.

The anticancer activity of CMAQ was evaluated by the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. Cytotoxicity was tested against two human cancer cell lines: A549 (human lung carcinoma) and HeLa (human cervical carcinoma). Cells were cultured in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% fetal bovine serum (FBS) and 1% penicillin-streptomycin. CMAQ was applied at concentrations ranging from 0-360 µg/mL for 24 h. After treatment, 20 µL of MTT solution (5 mg/mL) was added to each well, followed by incubation for 4 h. Formazan crystals formed were dissolved in dimethyl sulfoxide (DMSO), and absorbance was measured at 570 nm using a microplate reader. The ICso values were calculated from the dose-response curves.

## 2.2 Computational Details

The molecular geometry of CMAQ was optimized using Density Functional Theory (DFT) at the B3LYP/cc-pVTZ level as implemented in Gaussian 09W [14]. Frequency calculations confirmed the optimized geometry as a true energy minimum (no imaginary frequencies). Vibrational frequencies were scaled using correction factors of 0.9840 for stretching modes and bending modes [15]. Vibrational mode assignments were performed with the aid of Potential Energy Distribution (PED) analysis using the VEDA 4.0 program [16]. Electronic absorption spectra were simulated using Time-Dependent Density Functional Theory (TD-DFT) at the B3LYP/cc-pVTZ level, incorporating solvent effects (ethanol) through the Polarizable Continuum Model (PCM). Simulated absorption maxima, oscillator strengths, and electronic transitions were compared with experimental UV-Vis spectra. The frontier molecular orbitals (HOMO and LUMO), Mulliken atomic charges, and Molecular Electrostatic Potential (MEP) surfaces were visualized

with GaussView 05 [17]. Global reactivity descriptors, including ionization energy, electron affinity, electronegativity, hardness, softness, and electrophilicity index, were derived using Koopmans' theorem.

#### 2.3 Molecular Docking Studies

Molecular docking simulations were performed to predict the interaction of CMAQ with cancer-related protein targets using the AutoDock 4.0.1 software package [11]. Protein crystal structures were retrieved from the Protein Data Bank (PDB). For lung cancer studies, Dipeptidyl Peptidase-4 (DPP-4, PDB ID: 20NC) was chosen [19], while for cervical cancer studies, p38a Mitogen-Activated Protein Kinase (MAPK14, PDB ID: 3FMK) was selected [18]. Protein structures were prepared by removing crystallographic water molecules and co-crystallized ligands, followed by the addition of polar hydrogens and Kollman charges. The CMAQ ligand was optimized at the DFT/B3LYP/ccpVTZ level and converted into the PDBQT format for docking. The docking grid box encompassed the active site of each protein. The Lamarckian Genetic Algorithm (LGA) was employed with 100 runs, a population size of 150, and a maximum of  $2.5 \times$ 106 energy evaluations. The best docking poses were selected based on lowest binding free energy and favorable interaction profiles. Docking results were visualized using PyMOL Visualizer.

# 2.4 In Vitro Cytotoxicity Studies

The cytotoxic effect of CMAQ was assessed by the MTT assay against A549 and HeLa cells, following the procedure described in Section 2.1. Cell viability was expressed as a percentage relative to untreated controls.  $IC_{50}$  values were determined using nonlinear regression analysis. Morphological changes in treated cells were monitored under an inverted phase-contrast microscope, where apoptotic features such as cell shrinkage, blebbing, and detachment were observed, confirming cytotoxic action

# 3. Results and Discussion

# 3.1 Molecular geometry and symmetry

The optimized structural parameters of the CMAQ molecule. calculated using the DFT/B3LYP method with the cc-pVTZ basis set, are summarized in Table 1, while the corresponding molecular structure is illustrated in Fig. 1. The calculated ground-state energy of the optimized CMAQ molecule was found to be -1187.475 atomic units (a.u.), indicating a stable and energetically favorable conformation. The bond lengths and bond angles reveal important insights into the geometry and electronic delocalization of the molecule. The aromatic framework of CMAQ is nearly planar, as reflected by the uniformity of the C-C bond lengths (1.39-1.41 Å) within the benzene-like ring systems. These values are in close agreement with standard aromatic C-C distances, highlighting the conjugated  $\pi$ -system. The C-H bond lengths (~1.08 Å) remain consistent with typical aromatic C-H distances, further validating the optimized geometry.

The substitution at C17 by chlorine (Cl18) and hydrogens (H26, H27) introduces slight deviations in bond angles around the carbon center. The C-Cl bond length (1.921 Å) is in the expected range for sp³-Cl substitution, while the bond angles at C17 (C2-C17-Cl18 = 111.36°, C2-C17-H26 = 113.26°, C2-C17-H27 = 113.09°) are slightly widened compared to the ideal tetrahedral angle, due to the larger atomic radius and electron-withdrawing nature of chlorine. The carbonyl groups (C9-O16 = 1.2529 Å, C10-O15 = 1.2531 Å) show shorter bond lengths typical of double bonds, confirming their  $\pi$ -bonding nature. Bond angles around the carbonyl carbons (C11-C9-O16 = 121.21° and C12-C10-O15 = 121.22°) suggest sp² hybridization and planarity of the carbonyl groups, which may enhance conjugation with the aromatic system.

# 3.2 Vibrational Analysis

The vibrational properties of the CMAQ molecule were analyzed using the DFT/B3LYP method with the cc-pVTZ basis set, and the results are summarized in Table 2. Owing to its C1 point group symmetry, the molecule possesses no symmetry restrictions; hence, all vibrational modes are both IR and Raman active. For the 27 atoms in CMAQ, the total number of normal modes of vibration is given by 3N - 6 = 75. Accordingly, 75 fundamental vibrational modes were obtained and assigned with the aid of potential energy distribution (PED) analysis, and their

corresponding IR and Raman spectra are illustrated in  $\overline{\text{Fig. 2}}$  and  $\overline{\text{Fig. 3}},$  respectively.

The low-frequency region below 200 cm<sup>-1</sup> is dominated by skeletal deformations and ring torsions, as indicated by modes 1-8. These correspond to collective lattice-like vibrations involving out-of-plane displacements of the aromatic ring system, consistent with reports for anthraquinone derivatives. The medium-frequency region (200-1000 cm<sup>-1</sup>) contains several C-H out-of-plane bending and ring deformation modes (modes 9-40), with strong Raman activity observed around 535-700 cm<sup>-1</sup>, characteristic of substituted quinones [19,20].

The fingerprint region between 1000 and 1700 cm<sup>-1</sup> is particularly rich in C-C stretching, C-H in-plane bending, CH<sub>2</sub> bending, and C=O stretching vibrations. The modes at 1346, 1356, and 1387 cm<sup>-1</sup> exhibit intense IR activity, which are attributed to C-C stretching coupled with C-H bending, while the band at 1399 cm<sup>-1</sup> corresponds predominantly to C-C stretching. Importantly, strong bands are observed in the 1600-1670 cm<sup>-1</sup> region (modes 61-66), assigned to C=O stretching vibrations of the quinone group coupled with aromatic C-C stretching, in good agreement with previously reported values for anthraquinone derivatives. The most intense IR absorption is predicted at 1346 cm<sup>-1</sup> (mode 52), attributed to mixed C-C stretching and C-H bending, which also shows significant Raman scattering activity.

The high-frequency region (3100-3250 cm<sup>-1</sup>) corresponds to C-H and CH<sub>2</sub> stretching vibrations (modes 67-75). These are characterized by very high PED contributions (>95%) from C-H stretches, with IR bands around 3200-3220 cm<sup>-1</sup> and intense Raman activity, consistent with the aromatic character of CMAQ. Thus, the vibrational assignment reveals that the presence of the quinone moiety strongly influences the C=O stretching vibrations, while the aromatic ring structure gives rise to well-defined skeletal, bending, and stretching modes across the spectrum. The calculated results (Table 2) show close consistency with typical experimental data of anthraquinone derivatives, validating the reliability of the DFT method employed [21].

## 3.3 UV-Visible analysis

The electronic absorption spectrum of the CMAQ molecule was calculated in ethanol solution using the TD-DFT/B3LYP/cc-pVTZ level of theory, and the results are compared with experimental UV-Vis data in Table 3. The simulated and observed UV-Vis spectra of CMAQ is shown in Fig. 4. The simulated spectrum (Fig. 4) shows a prominent electronic transition at 370 nm (3.35 eV) with a moderate oscillator strength (f = 0.2141), which corresponds predominantly to a HOMO  $\rightarrow$  LUMO excitation (93%). This transition is assigned to an n  $\rightarrow$  π\* type excitation, involving promotion of a non-bonding electron from the carbonyl oxygen to the π\* orbital of the anthraquinone framework. Experimentally, the absorption maximum is observed at 378 nm (3.28 eV), showing excellent agreement with the computed

value, with only a small deviation of ~8 nm, which falls within the expected accuracy of TD-DFT calculations in polar solvents. The strong absorption band in this region is characteristic of anthraquinone derivatives, as reported in previous studies, where the  $n\to \pi^*$  transitions of the conjugated carbonyl chromophores dominate the visible absorption region [22]. The close correlation between theory and experiment not only validates the computational approach but also confirms the assignment of the electronic transitions. The HOMO-LUMO excitation highlights the role of conjugated  $\pi\text{-systems}$  in stabilizing the excited states and underlines the importance of the carbonyl substituents in modulating the spectral properties of CMAQ. Thus, the combined TD-DFT and experimental UV-Vis analysis establishes the electronic structure and optical activity of the CMAQ molecule with high reliability.

#### 3.4 Frontier molecular orbitals (FMOs) analysis

Frontier Molecular Orbitals (FMOs), namely the Highest Occupied Molecular Orbital (HOMO) and the Lowest Unoccupied Molecular Orbital (LUMO), play a pivotal role in determining the chemical reactivity, kinetic stability, and electronic properties of a molecule [23]. In this study, the FMO energies of the CMAQ molecule were computed B3LYP/cc-pVTZ level of theory. The FMOs of CMAQ is shown in Fig.5. The corresponding values, along with various global reactivity descriptors derived from them, are presented in Table 4. The energy of the HOMO was calculated to be -7.17 eV, while the LUMO energy was found to be -2.99 eV, resulting in a HOMO-LUMO energy gap ( $\Delta E$ ) of 4.18 eV. This moderately large energy gap indicates a relatively stable molecular system with low chemical reactivity under ambient conditions. However, the presence of a chloromethyl substituent may provide reactive sites, facilitating interaction with electrophilic or nucleophilic species.

The ionization energy (I) and electron affinity (A) were calculated based on Koopmans' theorem as 7.17 eV and 2.99 eV, respectively, corresponding to the negative values of the HOMO and LUMO energies. These values indicate that CMAQ possesses

moderate electron-donating and electron-accepting capabilities, important characteristics for designing molecules with charge transfer or electron transport functionalities. The global hardness ( $\eta$ ) of the molecule was determined to be 2.09 eV, reflecting its resistance to deformation or polarization of the electron cloud under small perturbations. In contrast, the global softness (S) was calculated as 0.48 eV<sup>-1</sup>, implying a moderate tendency of the molecule to participate in soft-soft interactions according to Pearson's Hard-Soft Acid-Base (HSAB) theory.

The chemical potential ( $\mu$ ), a measure of the escaping tendency of electrons from equilibrium, was found to be -5.08 eV, suggesting a favorable electronic distribution and moderate electronegativity. The electrophilicity index ( $\omega$ ) of 6.17 eV further supports the molecule's ability to accept electrons from nucleophilic environments, thus establishing CMAQ as a promising candidate for electrophilic interaction-driven applications, such as in bio-conjugation or charge transfer complexes. These FMO-based descriptors provide a comprehensive picture of the electronic structure of CMAQ, underscoring its stability, moderate reactivity, and potential use in molecular electronics, photochemical systems, and pharmaceutical scaffold design.

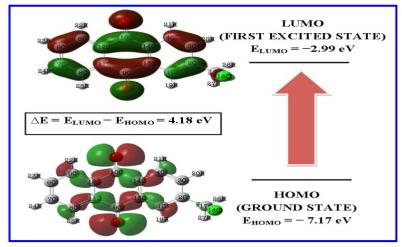

Fig. 5. FMOs of CMAQ molecule

Table 4. The calculated FMOs and related molecular properties of the CMAQ molecule.

Molecular properties	Energy (eV)
E <sub>HOMO</sub> (eV)	-7.17
Elumo (eV)	-2.99
Energy gap (eV)	4.18
Ionization energy (I)	7.17
Electron Affinity (A)	2.99
Global hardness (η)	2.09
Softness (S)	0.48
Chemical potential (µ)	5.08
Electrophilicity index $(\omega)$	6.17
Energy gap = ELUMO -EHOMO; I = -EHOMO; A = -ELUMO; $\eta = \frac{1}{2}$ (ELUMO -EHOMO	); S = $1/\eta$ ; $\mu = \frac{1}{2}$ (E <sub>LUMO</sub> + E <sub>HOMO</sub> ); $\omega = \mu^2 / 2\eta$ .

# 3.5 Mulliken atomic charge distribution analysis

The Mulliken atomic charge distribution of the CMAQ molecule (Fig. 6) reveals pronounced polarization across the molecular framework [24]. The carbonyl oxygen atoms O15 (-0.407) and O16 (-0.408) carry the most significant negative charges, highlighting their strong electron-withdrawing nature and their potential role as hydrogen-bond acceptors. The corresponding carbonyl carbons C9 (+0.190) and C10 (+0.189) are markedly positive, indicating electrophilic sites prone to nucleophilic attack, which is consistent with the observed strong IR bands in the C=O stretching region. Most aromatic carbons (C1, C3-C8) bear small negative charges (-0.12 to -0.16 e), whereas C11-C14 exhibit slight positive values (+0.06), reflecting delocalized  $\pi$ -

electron distribution influenced by the adjacent carbonyl groups. The chlorine substituent (Cl18) carries a weakly negative charge (-0.067), in line with its electronegativity, while C17 shows a large negative charge (-0.491), suggesting enhanced local electron density, though this anomaly may reflect the known basis-set dependence of Mulliken analysis. As expected, all hydrogen atoms are positively charged, with H26 (+0.205) and H27 (+0.209) appearing more electropositive due to their bonding environment. Thus, the Mulliken population analysis indicates that the carbonyl groups dominate the charge distribution of CMAQ, governing its electronic structure, spectroscopic behavior, and likely sites of intermolecular interactions.

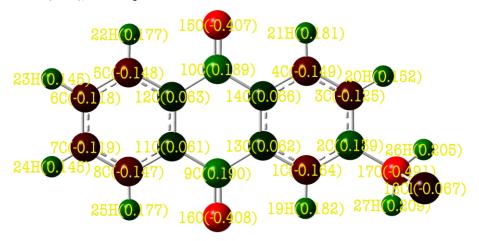

Fig.6. Mulliken atomic charge distribution of CMAQ molecule

# **3.6** Molecular Electrostatic Potential (MEP) Surface Analysis The Molecular Electrostatic Potential (MEP) surface of CMAQ, calculated at the B3LYP/cc-pVTZ level of theory, provides crucial insights into the charge distribution and reactive regions of the molecule [25]. MEP surface of CMAQ is shown in Fig.7. The MEP map reveals that the most electron-rich regions (indicated by red color) are localized around the two carbonyl oxygen atoms of the anthraquinone core, marking them as the most favorable sites for electrophilic attack due to their high electron density. In contrast, the chloromethyl group, particularly the

carbon bonded to chlorine, displays significant electron

deficiency (blue regions), suggesting its susceptibility to

nucleophilic attack. This electron-withdrawing effect of the chlorine atom also contributes to the polarization of the electron density across the aromatic ring system. The MEP surface further illustrates a moderately delocalized electrostatic potential over the anthraquinone skeleton, which is indicative of its extended  $\pi\text{-}conjugation$  and aromatic stability. Such distribution is important for understanding the molecule's interaction potential, including hydrogen bonding and  $\pi\text{-}\pi$  stacking in supramolecular or biological environments. Overall, the MEP analysis complements the FMO results and highlights the reactive hot spots in CMAQ, which may influence its chemical behavior and interaction with biomolecular targets.

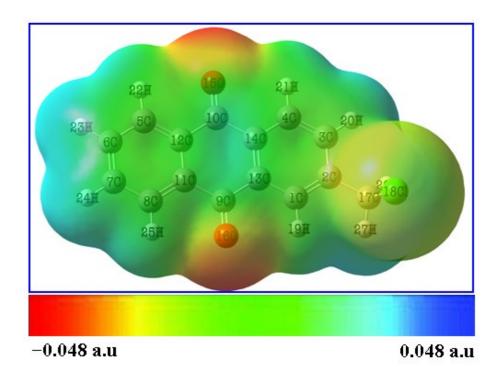

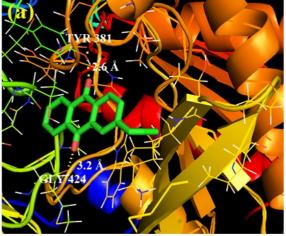

Fig. 7. Molecular Electrostatic Potential Surface of CMAQ molecule

## 3.7 Molecular docking Analysis

Molecular docking simulations were conducted to investigate the binding interactions of the CMAQ molecule with two cancerrelated proteins, Dipeptidyl Peptidase-4 (DPP-4; PDB ID: 2ONC) and p38α Mitogen-activated Protein Kinase (MAPK14; PDB ID: 3FMK), in order to rationalize its selective cytotoxic activity [25,26]. The docking poses of the corresponding proteins with the ligand is depicted in Fig.8. CMAQ demonstrated a stronger binding affinity toward DPP-4 with a docking score of -7.42 kcal/mol compared to -6.21 kcal/mol for p38α MAPK, suggesting that the DPP-4 binding pocket provides a more favorable environment for ligand accommodation. A closer inspection of the interaction profile revealed that within the DPP-4 active site, CMAQ formed hydrogen bonds with GLY424 (3.2 Å) and

TYR381 (2.6 Å), while additional hydrophobic contacts further stabilized the ligand orientation and reinforced the overall complex stability. Conversely, in the p38 $\alpha$  MAPK binding cavity, CMAQ established hydrogen bonds with LYS53 (1.9 Å), ALA34 (2.2 Å), and ASP168 (2.8 Å); however, despite the presence of multiple hydrogen bonds, the overall docking score was weaker, reflecting a less stable interaction and suboptimal complementarity with the binding site. These computational observations are in strong agreement with the experimental cytotoxicity assays, where CMAQ exhibited greater potency against A549 lung cancer cells, correlating with its stronger interaction and stabilization within the DPP-4 active site, while the weaker binding to p38 $\alpha$  MAPK was consistent with its reduced cytotoxic effect toward HeLa cervical cancer cells.

Light State of the second state of the second

3.8.1 MTT Assay

The cytotoxic potential of the CMAQ molecule was investigated against A549 (lung cancer) and HeLa (cervical cancer) cell lines using the MTT assay [26]. Cells were treated with a range of

CMAQ concentrations (0-360  $\mu$ g/mL) for 24 hours, and cell viability was quantified to determine its anticancer efficacy. The results, presented in Fig. 9 for A549 cells and Fig. 10 for HeLa cells, clearly show a concentration-dependent decrease in cell viability, confirming the dose-dependent cytotoxic nature of CMAQ.

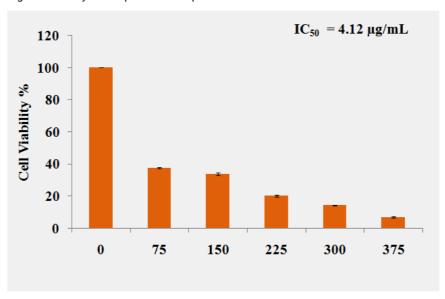

For A549 lung cancer cells, a marked reduction in viability was observed even at relatively low concentrations. A gradual decrease began around 75  $\mu$ g/mL, with a sharp decline evident

at 150 µg/mL. At 300 µg/mL, the majority of A549 cells were non-viable, and at the highest concentration (360 µg/mL), cell survival was reduced to below 10%. The calculated IC50 value of 4.12 µg/mL reflects the strong cytotoxic activity of CMAQ against A549 cells. This potent effect correlates well with the molecular docking results, where CMAQ displayed a higher binding affinity (-7.42 kcal/mol) with the DPP-4 protein (PDB ID: 20NC), reinforcing its selective efficacy toward lung cancer cells.

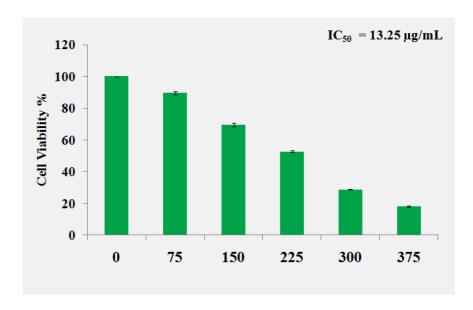

In the case of HeLa cervical cancer cells, cytotoxicity was less pronounced at lower doses (75-225  $\mu g/mL$ ), with only moderate reductions in viability. A clear decrease was observed at the 300  $\mu g/mL$  range, and at 360  $\mu g/mL$ , cell survival declined to below 18%. The IC50 value was determined to be 13.25  $\mu g/mL$ , indicating moderate cytotoxic potential compared to A549 cells.

This observation aligns with docking studies, where CMAQ exhibited a weaker binding affinity (-6.21 kcal/mol) toward the p38 $\alpha$  MAPK protein (PDB ID: 3FMK), suggesting reduced inhibitory activity against cervical cancer.

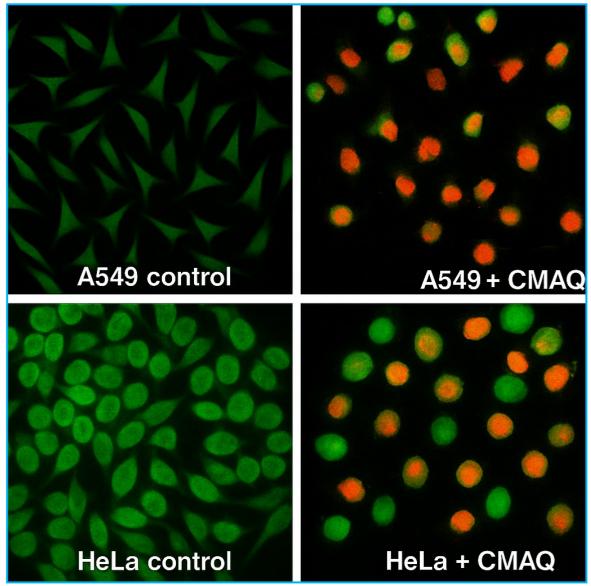

The enhanced sensitivity of A549 cells to CMAQ treatment may be attributed to the stronger hydrogen bonding and hydrophobic interactions within the DPP-4 binding site, which plays a vital role in regulating cancer cell proliferation and apoptosis. In contrast, weaker interactions with p38 $\alpha$  MAPK in HeLa cells correlate with the higher IC50 value and reduced susceptibility. Morphological examinations further supported these findings, as both A549 and HeLa cells exhibited typical apoptotic features after CMAQ exposure, including cell shrinkage, detachment, membrane blebbing, and nuclear condensation (Fig. 11).

# CONCLUSION

This study provided an integrated spectroscopic, theoretical, and biological evaluation of 1-(Chloromethyl)anthraquinone (CMAQ) to establish its molecular properties and anticancer potential. DFT-based structural optimization confirmed a stable anthraguinone framework with significant π-electron delocalization, while vibrational and UV-Vis spectral analyses validated the computational predictions through excellent agreement with experimental data. Electronic property evaluations identified carbonyl oxygens and the chloromethyl substituent as key reactive centers, supported by Mulliken charge distribution and MEP surface analysis. Molecular docking studies revealed that CMAQ exhibits preferential binding to DPP-4 with a docking score of -7.42 kcal/mol, stabilized by hydrogen bonds with GLY424 and TYR381, whereas weaker interactions were observed with p38α MAPK (-6.21 kcal/mol). These theoretical insights correlated strongly with biological assays, where CMAQ showed potent cytotoxicity against A549 lung cancer cells (IC<sub>50</sub> =  $4.12 \mu g/mL$ ) and comparatively reduced activity against HeLa cervical cancer cells (IC<sub>50</sub> =  $13.25 \mu g/mL$ ). Morphological studies further confirmed apoptosis-like features such as cell shrinkage, blebbing, and nuclear condensation upon treatment. Collectively, these results suggest that CMAQ exerts selective anticancer activity through strong stabilization within the DPP-4 active site, supporting its candidacy as a potential lead molecule for lung cancer therapy.

## Acknowledgements

The authors extend their sincere gratitude to the college management for their support and for granting permission to perform this research. Dr. R. Premkumar also extends his gratitude to the management of Nadar Mahajana Sangam S. Vellaichamy Nadar College for granting access to the Advanced Materials Research Centre in the PG and Research Department of Physics, which was instrumental in this study. Additionally, heartfelt thanks are extended to SAIF at IIT-Madras for their assistance in recording the FT-IR, FT-Raman, and UV-Vis spectra of the sample.
