#### Abstract

The present study was carried out to know the influence of physiological traits on the total fruit yield per vine in Luffa acutangula during 2012-2014. The genotype $L_{4}$ and $T_{4}$ were found to be good general combiners. The crosses $L_{4} \times T_{2}(1581.69 \mathrm{~g}), \mathrm{L}_{5} \times \mathrm{T}_{4}(1365.00 \mathrm{~g}), \mathrm{L}_{6} \times \mathrm{T}_{4}(1359.65 \mathrm{~g})$ and $\mathrm{L}_{2} \times \mathrm{T}_{4}(1224.48 \mathrm{~g})$ have been identified as good specific combiners for fruit yield per vine. The best performing parents can be used for further breeding programmes and hybrids could be exploited for cultivation.

## INTRODUCTION

The concept of Line x Tester was developed by Kempthorne (1957). It is a modified form of a top cross scheme. In case of top cross only one tester is used, while in case of Line x Tester several testers are used. The first step in evaluating the potential of new inbred lines is to cross them to a common parent and compare the performance of their hybrids. The common parent referred to as the tester and the hybrids produced are known as test crosses or top crosses. The tester is the same for all the inbred lines under evaluation (Singh and Narayanam, 2006). Ridge gourd (Luffa acutangula (Roxb.) L.) offers greater scope for exploitation of hybrid vigour on commercial scale to increase the productivity and production; otherwise it is the least exploited cucurbit vegetable. Niyaria and Bhalala (2001) reported that, the hybrids were early and gave higher yields in ridge gourd which helps to bridge the gap between the availability and requirement hence the crop is selected. The concept of combining ability helps in the identification of parents with good general and specific combing ability and also to determine the gene action involved in the expression of important quantitative traits. Reddy et al. (2013) reported that the possible exploitation of hybrid vigour in ridge gourd has been taken up at several research centers. However, very little systematic attention has been paid by plant breeders to study per se performance for earliness, yield and its components Reddy et al. (2013) as well as to physiological parameters. As such, so for there is no public sector or institutional commercial hybrids in ridge gourd in India, though few private hybrids from leading seed production companies are being cultivated by growers. The investigation on heterosis
with regard to physiological growth parameters in cucurbits like ridge gourd as well as in most of the important vegetables viz., okra, onion, potato etc. is meager. Hence, the present investigation was undertaken to its precision and versatility with an objective to select elite parental lines which can be utilized for future hybridization programmes, combining ability of selected ridge gourd local cultivars for fruit and the best performing hybrids for commercial cultivation.

## MATERIALS AND METHODS

The present investigation was carried out at Kittur Rani Channamma College of Horticulture, Arabhavi, Karnataka. The experimental material consists of ten parents viz; Deepthi ( $L_{1}$ ), Mudigere Local $\left(L_{2}\right)$, Dalasanur Local $\left(L_{3}\right)$, Arabhavi Local $\left(L_{4}\right)$, Kolar Local ( $\mathrm{L}_{5}$ ), Arka Sumeet ( $\mathrm{L}_{6}$ ) used as lines (females) and Jaipur Long $\left(T_{1}\right)$, Gadag Local $\left(T_{2}\right)$, Ghataprabha Local $\left(T_{3}\right)$ and Arka Sujata ( $\mathrm{T}_{4}$ ) as testers (males) and mated as per Line x Tester mating model of Kempthorne (1957) and Thus a total of 24 hybrids were synthesized by making crosses between lines and the testers during kharif 2012. All the 24 hybrids along with their corresponding ten parents and one commercial check variety viz; Naga were evaluated in a randomized block design in three replications during summer 2014. The data was subjected to the analysis of variance for randomized block design as suggested by Panse and Sukhatme (1978). Observations on five randomly selected plants were recorded for various yield attributing traits to see the performance of parents and hybrids over the checks. Variance due to general combining ability (GCA) of parents and specific combining
ability (SCA) of crosses (hybrids) were worked out on the Line x Tester analysis procedure developed by Kempthorne (1957).

## RESULTS AND DISCUSSION

The analysis of variance using Line x Tester analysis showed significant treatment difference for all the characters studied are presented in Table 1. The mean sum of squares due to gca and sca were significant for all characters, indicated the importance of both additive and non-additive genetic components for traits under study. Similar results were reported by Singh et al. (2013), Singh et al. (2014) and Reddy et al. (2013). Tyagi et al. (2010) also found significant gca and sca for the traits like fruits per vine, fruit length and fruit girth. The ratio of variance gca to variance sca suggested the preponderance of non additive gene action for all the characters suggested by Lodam et al. (2009).
Absolute growth rate at 45-90 DAS of vine and leaf were observed lowest in $L_{5}$ ( 2.21 and $3.71 \mathrm{~g} /$ day respectively) and highest in $L_{2}$ ( 10.92 and $4.63 \mathrm{~g} /$ day respectively) among the lines. Among the testers, with respect to vine, highest was observed in $\mathrm{T}_{2}(8.69 \mathrm{~g} /$ day $)$ and lowest was expressed in $\mathrm{T}_{4}$ ( $7.54 \mathrm{~g} /$ day) and with respect to leaf, highest was observed in $\mathrm{T}_{4}(8.55 \mathrm{~g} /$ day $)$ and lowest was expressed in $\mathrm{T}_{3}(4.18 \mathrm{~g} /$ day $) . \mathrm{L}_{1}$ $\mathrm{x} \mathrm{T}_{3}$ ( $13.47 \mathrm{~g} /$ day $)$ exhibited the highest AGR with respect to vine and $L_{4} \times T_{3}$ was with highest $A G R$ with respect to the leaf at 45-90 DAS. The commercial check, NAGA possessed the $10.68 \mathrm{~g} /$ day (for vine) and $4.46 \mathrm{~g} /$ day (for leaf). This work is first time in ridge gourd. The parents which possess the higher value of AGR resulted in higher yield per vine and findings were in consonance with Meena et al. (2013) in mustard, Sharma et al. (1996) in cauliflower and Chavan et al. (2010) in tomato.
CGR of vine and leaf (45-90 DAS) were observed highest in $\mathrm{L}_{2}$ (20.22 and $8.58 \mathrm{~g} .^{-2} . \mathrm{day}^{-1}$ respectively) and lowest in $\mathrm{L}_{5}$ ( 4.08 and $6.88 \mathrm{~g} . \mathrm{m}^{-2}$. day $^{-1}$ respectively) among the lines. Among the testers, with respect to vine, highest was observed in $\mathrm{T}_{2}\left(16.09 \mathrm{~g} . \mathrm{m}^{-2}\right.$. day $\left.^{-1}\right)$ and lowest was expressed in $\mathrm{T}_{4}(13.97$ g. $\mathrm{m}^{-2}$. day $^{-1}$ ) and with respect to leaf, highest was observed in $\mathrm{T}_{4}\left(15.83 \mathrm{~g} . \mathrm{m}^{-2}\right.$. day $^{-1}$ ) and lowest was expressed in $\mathrm{T}_{3}(7.74 \mathrm{~g}$. $\mathrm{m}^{-2}$. $\mathrm{day}^{-1}$ ). The commercial check, NAGA possessed the 19.78 g. $\mathrm{m}^{-2}$. day ${ }^{-1}$ (for vine) and $8.27 \mathrm{~g} . \mathrm{m}^{-2}$.day ${ }^{-1}$ (for leaf). These results were conformity with the results of Sharma et al. (1996) in cauliflower, Ninganur (2002) in cotton and Chavan et al. (2010) in tomato and they reported that is the rate of increase of dry weight per unit land area per unit time. CGR is also the product of leaf area index and net assimilation rate. CGR increases as LAI increases to an optimum because of greater light interception the variation in the biomass is further supported by growth analysis studies.
Relative growth rate at 45-90 DAS of vine varied from 0.15 $\mathrm{mg} . \mathrm{m}^{-2}$. day ${ }^{-1}\left(\mathrm{~L}_{5}\right)$ to $0.77 \mathrm{mg} . \mathrm{m}^{-2}$. day ${ }^{-1}\left(\mathrm{~L}_{2}\right)$ among the lines, $0.53 \mathrm{mg} \cdot \mathrm{m}^{-2}$. day $^{-1}\left(\mathrm{~T}_{1}\right)$ to $0.64 \mathrm{mg} \cdot \mathrm{m}^{-2}$. day $^{-1}\left(\mathrm{~T}_{2}\right)$ among the testers and $0.29 \mathrm{mg} . \mathrm{m}^{-2}$. day ${ }^{-1}\left(\mathrm{~L}_{4} \times \mathrm{T}_{1}\right)$ to $0.79 \mathrm{mg} \cdot \mathrm{m}^{-2}$. day ${ }^{-1}\left(\mathrm{~L}_{1} \times\right.$ $\mathrm{T}_{4}$ ) among the crosses. Relative growth rate at 45-90 DAS of leaf varied from $0.16 \mathrm{mg} . \mathrm{m}^{-2}$. day ${ }^{-1}\left(\mathrm{~L}_{4}\right)$ to $0.23 \mathrm{mg} \cdot \mathrm{m}^{-2}$. day $^{-1}\left(\mathrm{~L}_{1}\right)$ among the lines, $0.22 \mathrm{mg} . \mathrm{m}^{-2}$. day $^{-1}\left(\mathrm{~T}_{1}\right)$ to $0.45 \mathrm{mg} \cdot \mathrm{m}^{-2}$.day ${ }^{-1}$ $\left(T_{4}\right)$ among the testers and $0.02 \mathrm{mg} . \mathrm{m}^{-2}$. day ${ }^{-1}\left(\mathrm{~L}_{3} \times \mathrm{T}_{4}\right)$ to 0.39 $\mathrm{mg} . \mathrm{m}^{-2}$. day ${ }^{-1}\left(\mathrm{~L}_{4} \times \mathrm{T}_{3}\right)$ among the crosses. The commercial
 rate, RGR: Relative growth rate, NAR: Nett assimilation rate

DAS: Days after sowing;GCA: Variances due to general combining ability; SCA: Variances due to specific combining ability; LA: Leaf area ; LAI: Leaf area index; SLA: Specific leaf area ; SLW: Specific leaf weight ; AGR: Absolute growth rate; CGR: Crop growth rate ; RGR: Relative growth rate
check, NAGA possessed the $0.75 \mathrm{mg} . \mathrm{m}^{-2}$. day ${ }^{-1}$ (for vine) and $0.22 \mathrm{mg} . \mathrm{m}^{-2}$. day ${ }^{-1}$ (for leaf). Chavan et al. (2010) reported that RGR is the rate of increase of dry weight per unit weight already present per unit time and it decreases as the stress level increases. These results were conformity with the results of Sharma et al. (1996) in cauliflower and Ninganur (2002) in cotton.
NAR at 45-90 DAS of vine varied from $0.19 \mathrm{mg} \cdot \mathrm{m}^{-2}$. day $^{-1}\left(\mathrm{~L}_{5}\right)$ to $0.77 \mathrm{mg} \cdot \mathrm{m}^{-2}$ day ${ }^{-1}\left(\mathrm{~L}_{2}\right)$ among the lines, $0.45 \mathrm{mg} \cdot \mathrm{m}^{-2}$. day $^{-1}\left(\mathrm{~T}_{3}\right)$ to $0.78 \mathrm{mg} \cdot \mathrm{m}^{-2}$ day ${ }^{-1}\left(\mathrm{~T}_{2}\right)$ among the testers and $0.28 \mathrm{mg} \cdot \mathrm{m}^{-2}$. day ${ }^{-1}$ $\left(L_{4} \times T_{1}\right)$ to $0.84 \mathrm{mg} \cdot \mathrm{m}^{-2}$. day ${ }^{-1}\left(\mathrm{~L}_{1} \times \mathrm{T}_{4}\right)$ among the crosses. NAR at $45-90$ DAS of leaf varied from $0.15 \mathrm{mg} \cdot \mathrm{m}^{-2}$ day $^{-1}\left(\mathrm{~L}_{3}\right)$ to 0.32 $\mathrm{mg} \cdot \mathrm{m}^{-2}$. day $^{-1}\left(\mathrm{~L}_{2}\right)$ among the lines, $0.27 \mathrm{mg} \cdot \mathrm{m}^{-2}$. day $^{-1}\left(\mathrm{~T}_{3}\right)$ to 0.55 $\mathrm{mg} \cdot \mathrm{m}^{-2}$ day $^{-1}\left(\mathrm{~T}_{4}\right)$ among the testers and $0.05 \mathrm{mg} \cdot \mathrm{m}^{-2} \cdot$ day $^{-1}\left(\mathrm{~L}_{3} \mathrm{x}\right.$ $T_{4}$ ) to $0.53 \mathrm{mg} \cdot \mathrm{m}^{-2}$. day $^{-1}\left(\mathrm{~L}_{2} \times \mathrm{T}_{3}\right)$ among the crosses. The commercial check, NAGA possessed the $1.20 \mathrm{mg} . \mathrm{m}^{-2}$. day $^{-1}$ (for vine) and $0.50 \mathrm{mg}^{\mathrm{m}} \mathrm{m}^{-2}$. day ${ }^{-1}$ (for leaf). AGR, CGR, RGR and NAR indicate better growth and development which in turn depends on the leaf area. Net assimilation rate is the rate of increase of dry weight per unit area of leaf per unit time. These results were conformity with the results of Ninganur (2002) in cotton and Chavan et al. (2010) in tomato.
Leaf area on 45 DAS varied from $41.42 \mathrm{~cm}^{2}\left(\mathrm{~L}_{5}\right)$ to $176.17 \mathrm{~cm}^{2}$ $\left(\mathrm{L}_{3}\right)$ among the lines, $63.77 \mathrm{~cm}^{2}\left(\mathrm{~T}_{1}\right)$ to $176.17 \mathrm{~cm}^{2}\left(\mathrm{~T}_{4}\right)$ among the testers and $42.58 \mathrm{~cm}^{2}\left(\mathrm{~L}_{6} \times \mathrm{T}_{2}\right)$ to $112.49 \mathrm{~cm}^{2}\left(\mathrm{~L}_{4} \times \mathrm{T}_{3}\right)$ among the crosses. Whereas, Leaf area at 90 DAS ranged from $52.71 \mathrm{~cm}^{2}\left(\mathrm{~L}_{1}\right)$ to $74.03 \mathrm{~cm}^{2}\left(\mathrm{~L}_{3}\right)$ among the lines, 53.09 $\mathrm{cm}^{2}\left(\mathrm{~T}_{2}\right)$ to $62.49 \mathrm{~cm}^{2}\left(\mathrm{~T}_{1}\right)$ among the testers and $86.08 \mathrm{~cm}^{2}\left(\mathrm{~L}_{6}\right.$ $\left.x \mathrm{~T}_{3}\right)$ to $211.02 \mathrm{~cm}^{2}\left(\mathrm{~L}_{4} \times \mathrm{T}_{2}\right)$ among the crosses. The commercial check, NAGA possessed the $64.18 \mathrm{~cm}^{2}$ ( 45 DAS ) and 21.29 $\mathrm{cm}^{2}$ (90 DAS). Leaf area being the photosynthetic surface area, which plays an important role in determining total biomass accumulation and quality of photosynthates available for yield production. The highest leaf area was observed in $L_{4} \times T_{1}$ ( $211.02 \mathrm{~cm}^{2}$ ) that might have lead to more assimilation of photosynthates and contributed to highest fruit yield. This was akin with the results of Kore et al. (2003) in bitter gourd
and Reddy et al. (2013) in ridge gourd.
Specific Leaf area on 45 DAS varied from $4.62 \mathrm{~cm}^{2} / \mathrm{g}\left(\mathrm{L}_{5}\right)$ to $23.25 \mathrm{~cm}^{2} / \mathrm{g}\left(\mathrm{L}_{3}\right)$ among the lines, $6.78 \mathrm{~cm}^{2} / \mathrm{g}\left(\mathrm{T}_{1}\right)$ to 14.17 $\mathrm{cm}^{2} / \mathrm{g}\left(\mathrm{T}_{3}\right)$ among the testers and $3.05 \mathrm{~cm}^{2} / \mathrm{g}\left(\mathrm{L}_{5} \times \mathrm{T}_{2}\right)$ to 10.01 $\mathrm{cm}^{2} / \mathrm{g}\left(\mathrm{L}_{4} \times \mathrm{T} 3\right)$ among the crosses. Specific Leaf area at 90 DAS ranged from $5.44 \mathrm{~cm}^{2} / \mathrm{g}\left(\mathrm{L}_{4}\right)$ to $7.70 \mathrm{~cm}^{2} / \mathrm{g}\left(\mathrm{L}_{3}\right)$ among the lines, $5.48 \mathrm{~cm}^{2} / \mathrm{g}\left(\mathrm{T}_{2}\right)$ to $6.34 \mathrm{~cm}^{2} / \mathrm{g}\left(\mathrm{T}_{3}\right)$ among the testers and $5.48 \mathrm{~cm}^{2} / \mathrm{g}\left(\mathrm{L}_{6} \times \mathrm{T}_{3}\right)$ to $12.98 \mathrm{~cm}^{2} / \mathrm{g}\left(\mathrm{L}_{4} \times \mathrm{T}_{2}\right)$ among the crosses. The commercial check, NAGA possessed the 8.10 $\mathrm{cm}^{2} / \mathrm{g}(45 \mathrm{DAS})$ and $2.14 \mathrm{~cm}^{2} / \mathrm{g}$ (90 DAS). Specific leaf area is the ratio of assimilating area to its dry weight. SLA is maximum in open area crops because of high photosynthetic surface area (Radford, 1962). The highest specific leaf area was observed in $L_{4} \times T_{2}\left(12.98 \mathrm{~cm}^{2} / \mathrm{g}\right)$ that might have lead to more assimilation of photosynthates and contributed to highest fruit yield. This was akin with the results of Kore et al. (2003) in bitter gourd and Reddy et al. (2013) in ridge gourd.
Number of fruits per vine varied significantly among the genotypes, which ranged from $6\left(T_{2}\right)$ to $6.5\left(T_{1}\right)$ among testers, $5.25\left(\mathrm{~L}_{4}\right)$ to $6.75\left(\mathrm{~L}_{2}\right)$ among lines and $6.5\left(\mathrm{~L}_{5} \mathrm{X} \mathrm{T}_{1}\right)$ to $7.5\left(\mathrm{~L}_{5} \times \mathrm{T}_{4}\right)$ among crosses. The commercial check, NAGA possessed the 7.00 fruits per vine. Anand (2012) in ridge gourd and Rathod (2007) in bitter gourd reported that number of fruits per vine had a high relationship to the total yield. For the trait, average fruit weight, the genotypes ranged from $117.43 \mathrm{~g}\left(\mathrm{~T}_{3}\right)$ to 148.4 $g\left(T_{2}\right)$ among testers, $118.06 \mathrm{~g}\left(\mathrm{~L}_{1}\right)$ to $189.75 \mathrm{~g}\left(\mathrm{~L}_{4}\right)$ among lines and $98.85\left(\mathrm{~L}_{3} \times \mathrm{T}_{3}\right)$ to $194.73 \mathrm{~g}\left(\mathrm{~L}_{4} \times \mathrm{T}_{2}\right)$ among crosses. The commercial check, NAGA possessed the 157.00 g fruit weight. The trait fruit weight had a high relationship to the total yield per vine. The results were consonance with the scientists Anand (2012) and Rathod (2007) in bitter gourd.

Lines, testers and hybrid combinations used in investigation differed significantly for the character fruit length and it varied from $20.23 \mathrm{~cm}\left(\mathrm{~T}_{1}\right)$ to $21.88 \mathrm{~cm}\left(\mathrm{~T}_{4}\right)$ among testers, $18.35\left(\mathrm{~L}_{1}\right)$ to $22.73 \mathrm{~cm}\left(\mathrm{~L}_{4}\right)$ among lines and $21.85\left(\mathrm{~L}_{3} \mathrm{X}_{4}\right)$ to 34.90 cm $\left(L_{4} X T_{4}\right)$ among crosses. The commercial check, NAGA had

20.25 cm fruit length. For fruit diameter, among the lines, L5 was having 21.61 mm and $\mathrm{L}_{4}$ was with 33.1 mm . the genotype $\mathrm{T}_{2}$ was with 23.8 mm of fruit diameter whereas, $\mathrm{T}_{4}$ was having the 28.2 mm among testers and $20.1 \mathrm{~mm}\left(\mathrm{~L}_{3} \times \mathrm{T}_{3}\right)$ to 34.02 mm $\left(L_{4} \times T_{2}\right)$ was a range among crosses. The commercial check, NAGA had 29.70 mm fruit diameter. Tyagi et al. (2010) also reported that number of fruits per vine, fruit length and girth had a high relationship to the total yield. These results are conformity with the Anand (2012) and Reddy et al. (2013) in ridge gourd.
The parameters like per cent fruit set, fruit length, fruit girth, number of fruits per vine and average fruit weight are important for contributing to the total yield. For the trait fruit yield per vine which ranged from $729.67 \mathrm{~g}\left(\mathrm{~T}_{3}\right)$ to $886.5 \mathrm{~g}\left(\mathrm{~T}_{2}\right)$ among testers, $628 \mathrm{~g}\left(\mathrm{~L}_{1}\right)$ to $1085 \mathrm{~g}\left(\mathrm{~L}_{6}\right)$ among lines and the minimum, 741.95 g fruits were with the hybrid $\left(\mathrm{L}_{3} \times \mathrm{T}_{3}\right)$ and high heterotic hybrid was ( 1581.69 g ) $\mathrm{L}_{4} \times \mathrm{T}_{2}$ among crosses. The commercial check, NAGA had 1088.25 g fruit yield per vine.
The hybrid $L_{4} \times T_{2}$ showed maximum number of fruits per vine and leaf area might have contributed to highest yield per vine ( 1581.69 g ). The hybrid $\mathrm{L}_{5} \times \mathrm{T}_{4}$ also showed significantly superior performance for yield per vine ( 1365.00 g ) which might due to highest number of female flowers, fruit girth, average fruit weight and least sex ratio. The mean yield per vine was highest ( 1088.25 g ) in hybrids compared to check variety (Table 2). The high yielding hybrids in the order of merit are $L_{4} \times T_{2}, L_{5} \times T_{4}$ and $L_{6} \times T_{4}$ has surpassed the yield of parents and the commercial check. The high yield in these $F_{1}$ hybrids has been attributed due to early maturity, increased number of fruits per vine and increase in fruit length and fruit weight. These results were in confirmation with Kadam et al. (1995), Narayanankutty et al. (2006) in snake gourd, Bharathi et al. (2006) Gayen and Hossain (2006), Kumar et al. (2007), Rathod (2007) in bottle gourd, Anand (2012) in ridge gourd, Islam et al. (2009) in bitter gourd and Singh et al. (2013) in bitter gourd. The parents differ significantly for all the characters except AGR and NAR of leaf 45-90 DAS, CGR, leaf area, leaf area index, specific leaf area and specific leaf weight at 90 DAS. The crosses differed significantly for all the characters studied except diameter of vine at 45 and 90 DAS and NAR of leaf and vine, number of fruits per vine and fruit length. Mean sum of square for the parents vs. crosses differed significantly for all the characters except NAR of leaf and vine, which indicated that heterosis for other traits considered. There was greater diversity among lines than testers based on the significant mean sum of squares for majority of the traits. The interaction of lines and testers differed significantly for all the traits. Singh et al. (2013) reported that the data revealed to contain higher magnitude of SCA variance as compared to GCA variances for all the characters which indicated the predominance of non additive gene action (Table 3).

## General combing ability effects

The gca effects of lines and testers (Table 4) revealed significant differences among the lines and testers. Line $L_{4}$ was a good general combiner and appeared to transmit additive genes for important yield attributes viz., leaf area at 90 DAS (41.61), specific leaf area at 90 DAS (1.97), AGR of leaf (3.28), CGR of leaf (6.03) and RGR of leaf (0.10) at period of 45-90 DAS, average fruit weight (20.49), fruit length (2.65), fruit diameter

(4.67) and fruit yield per vine (139.24). The line $L_{1}$ seemed to possess additive genes for AGR of vine (1.43), CGR of vine (2.65), RGR of vine (0.11) and NAR of vine (0.14). The line $L_{2}$ appeared to possess additive genes for yield attributes such as leaf area (19.77) and specific leaf area (0.94) at 90 DAS, AGR of leaf (2.44), CGR of leaf (4.52), RGR of leaf (0.08) and NAR of leaf (0.10) at 45-90 DAS, CGR of vine (2.65) and RGR of vine (0.11) at 45-90 DAS. Among the testers, $\mathrm{T}_{2}$ was a good general combiner and appeared to transmit additive genes for important yield attributes viz., leaf area (9.57) and specific leaf weight at 45 DAS (0.019). The method followed by Arunachalam and Bandopadyaya, (1979) was followed to designate the lines and testers as high (H) and low (L) overall general combiners (Table.6). The results of gca effects are similar with Anand (2012) in ridge gourd and Rathod (2007) in bitter gourd Accordingly, nearly 50 per cent of them were good general combiners and among the testers, except $T_{4}$ all expressed average overall gca status which suggested its ability to transmit additive genes for the traits.

## Specific combining ability effects

High specific combining ability (sca) results mostly from dominance and interaction effects existing between the hybridizing parents. The cross $L_{4} \times T_{2}$ exhibited sca effect in positive desirable direction for three characters namely leaf area at 90 DAS (41.82) and specific leaf area (SLA) at 90 DAS (2.84) (Table 5). As the leaf area increases the photosynthetic capacity of the plant also increases and directly proportional to the average yield per vine (Ahmad, 2005). SLA is maximum in open area condition because of high photosynthetic surface area (Radford, 1962). The crosses $L_{1} \times T_{3}$ and $L_{5} \times T_{1}$ exhibited positive significant sca effect for average fruit weight whereas $L_{6} \times T_{4}$ was with higher amount of sca effect for total yield per vine. The final yield and yield attributing characters are basically governed by the vegetative growth as dry matter production and its distribution. Yield is the function of many yield contributing characters like number of fruits and average fruit weight (Islam et al., 2009 in bitter gourd). Among the $24 \mathrm{~F}_{1}$ hybrids, 4 hybrids are highly heterotic than parents and commercial check. The hybrid, $L_{4} \times T_{2}$ was high heterotic than rest of all. Nearly 50 per cent of the $F_{1}$ hybrids had high (H) overall status (Table 6). The cross $L_{4} \times T_{2}$ had a high overall status and had positive sca effects for important traits such as average fruit weight and fruit yield per vine. It was seen that the best crosses for majority of the characters involved at least one high general combining parent. Therefore, it is desirable to select one parent with high general combining ability and other with low general combining ability for obtaining crosses with high sca effects. The above results have an important bearing on future breeding strategies. The presence of non additive gene action can be exploited to

Table 6: Analysis of general combining ability status of parent's and specific combining ability status for hybrids for physiological, biochemical and yield traits in ridge gourd

Analysis of specific combining ability status for hybrids

produce hybrids with high yield. In this study the parents $L_{6}$, $L_{4}$, were good general combiners for various characters taken under study, in this perspective they could be exploited further in different breeding programmes. The promising hybrids like $L_{4} \times T_{2}, L_{5} \times T_{4}, L_{6} \times T_{4}$ and $L_{3} \times T_{4}$ which are superior yielders than the checks can be further subjected to selection to isolate desirable transgressive segregants.
